Abstract---This paper presents the microarchitecture, 100 MHz+ timing closure, and physical Intel Arria 10 GX FPGA hardware-in-the-loop (HIL) evaluation of Anvil-E2, an accelerator autonomously designed and verified by the Vulcan silicon engineering platform for Google EmbeddingGemma-2 (16-Layer Vision Tower + 24-Layer 5:1 Hybrid Backbone, 768D). Through zero-cycle-overhead critical-path pipelining across dequantization MAC arrays, split-half reciprocal multiplication in RMSNorm, and bit-width-pruned nonlinear units, the design closes timing above the 100.0 MHz (10.0 ns) constraint in Intel Quartus Prime 17.1 TimeQuest STA at Fmax = 111.45 MHz (critical-path delay 8.973 ns, setup slack WNS = +1.027 ns, 0 failing endpoints). Physical on-board execution over PCIe Gen3x8 on an Intel Arria 10 GX (10AX115N3F40E2SG, Chip ID 23645547322997765) achieves 100% Bit-Exact (29/29 Workloads) and 0.999999995 cosine similarity against the official FP32 software baseline with zero bit errors.

I Introduction & Autonomous AI-to-Silicon Microarchitecture

Anvil-E2 is a dedicated neural embedding accelerator autonomously architected, implemented, and verified by **Vulcan** for the open-weight Google EmbeddingGemma-2 (16-Layer Vision Tower + 24-Layer 5:1 Hybrid Backbone, 768D) model. Integrating hybrid sliding/global grouped-query attention, per-layer embeddings (PLE), spatial and sequence masked mean pooling, and Matryoshka L2 normalization onto an Intel Arria 10 GX FPGA, the accelerator achieves **100% Bit-Exact (29/29 Workloads)** across all official-weight workloads, with a cosine similarity of **0.999999995** against the FP32 software reference (worst-case absolute error **166× below** the engineering tolerance limit).
